

Taskflow: A General-purpose Task-parallel Programming System

Dr. Tsung-Wei (TW) Huang, Assistant Professor
Department of Electrical and Computer Engineering
University of Wisconsin at Madison, Madison, UT

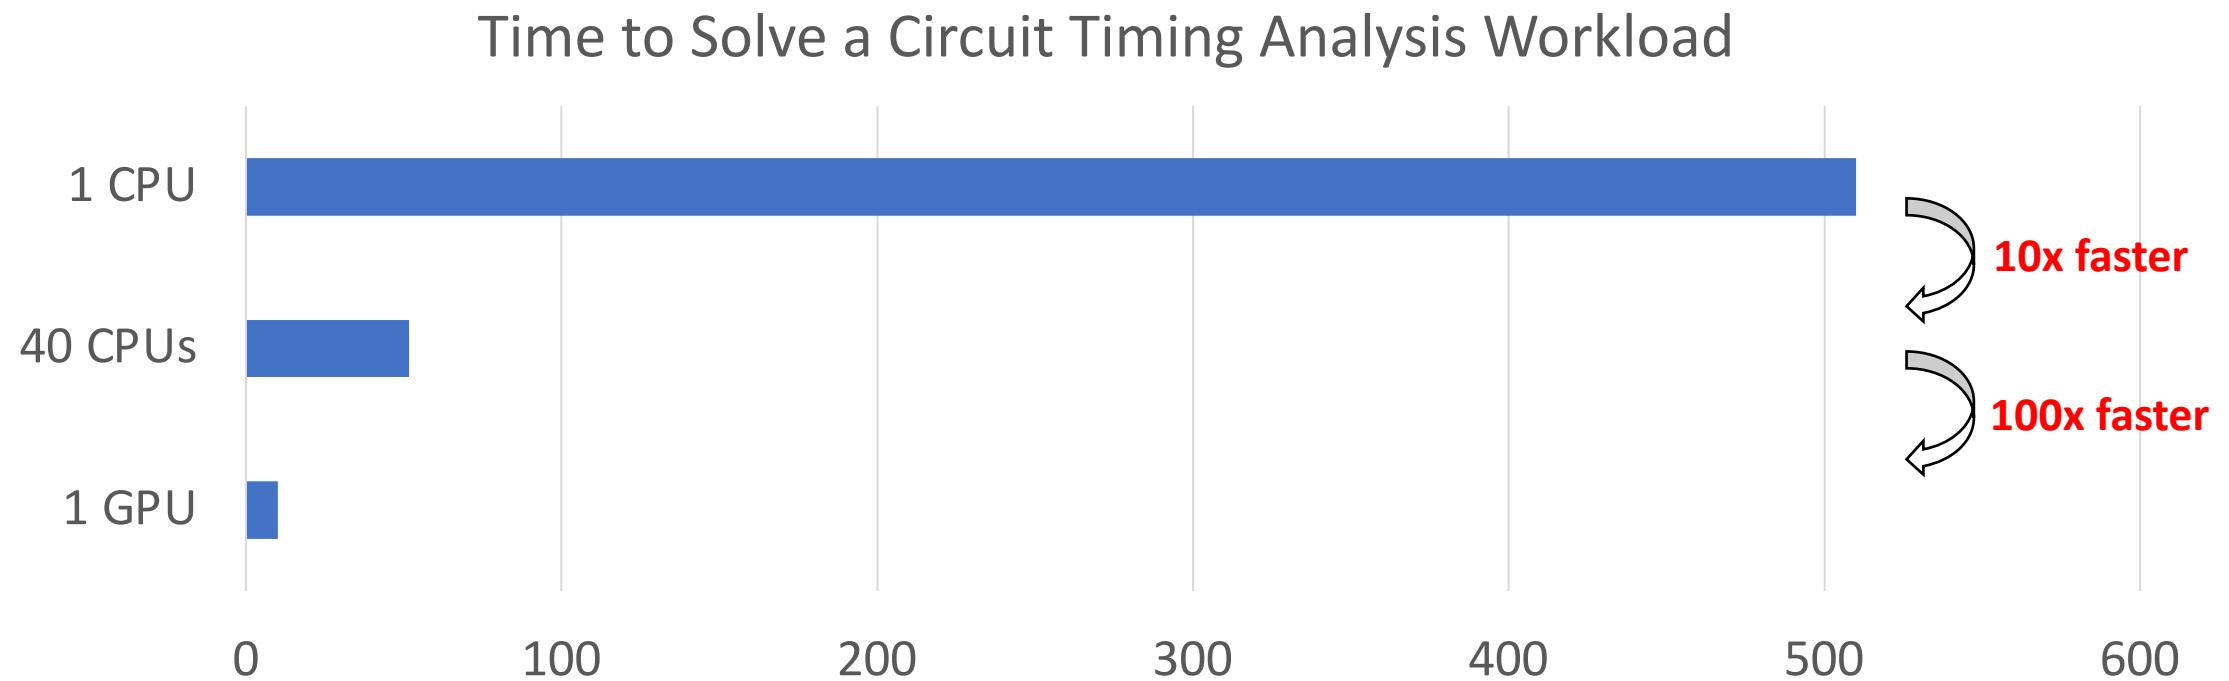

<https://tsung-wei-huang.github.io/>

Why Parallel/Heterogeneous Computing?

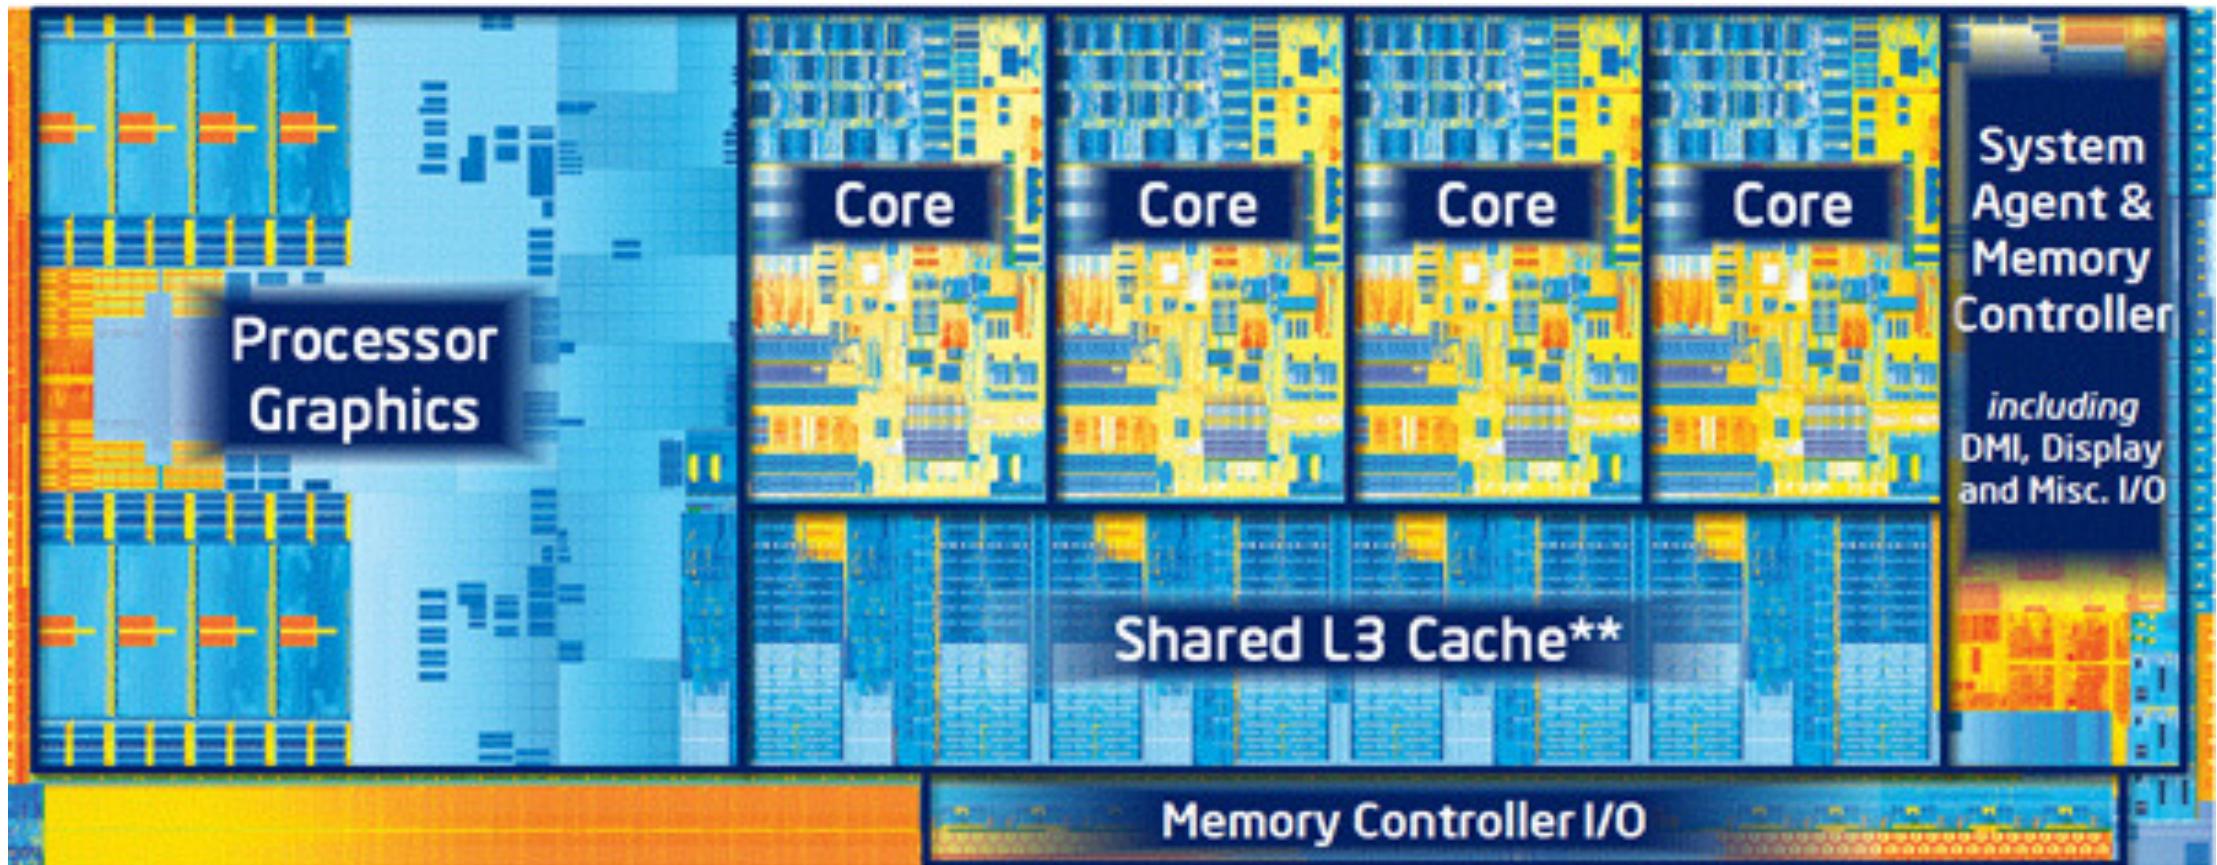

- It's critical to advance your application performance

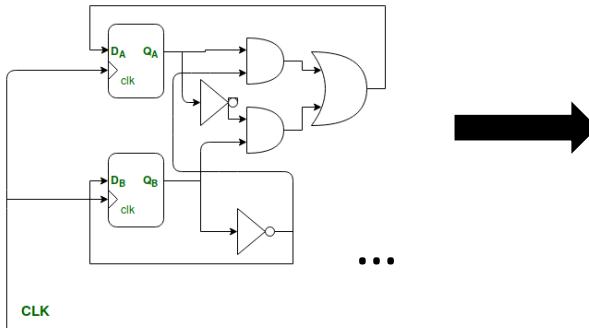

Your Computer is Already Parallel

- Intel i7-377K CPU (four cores to run your jobs in parallel)

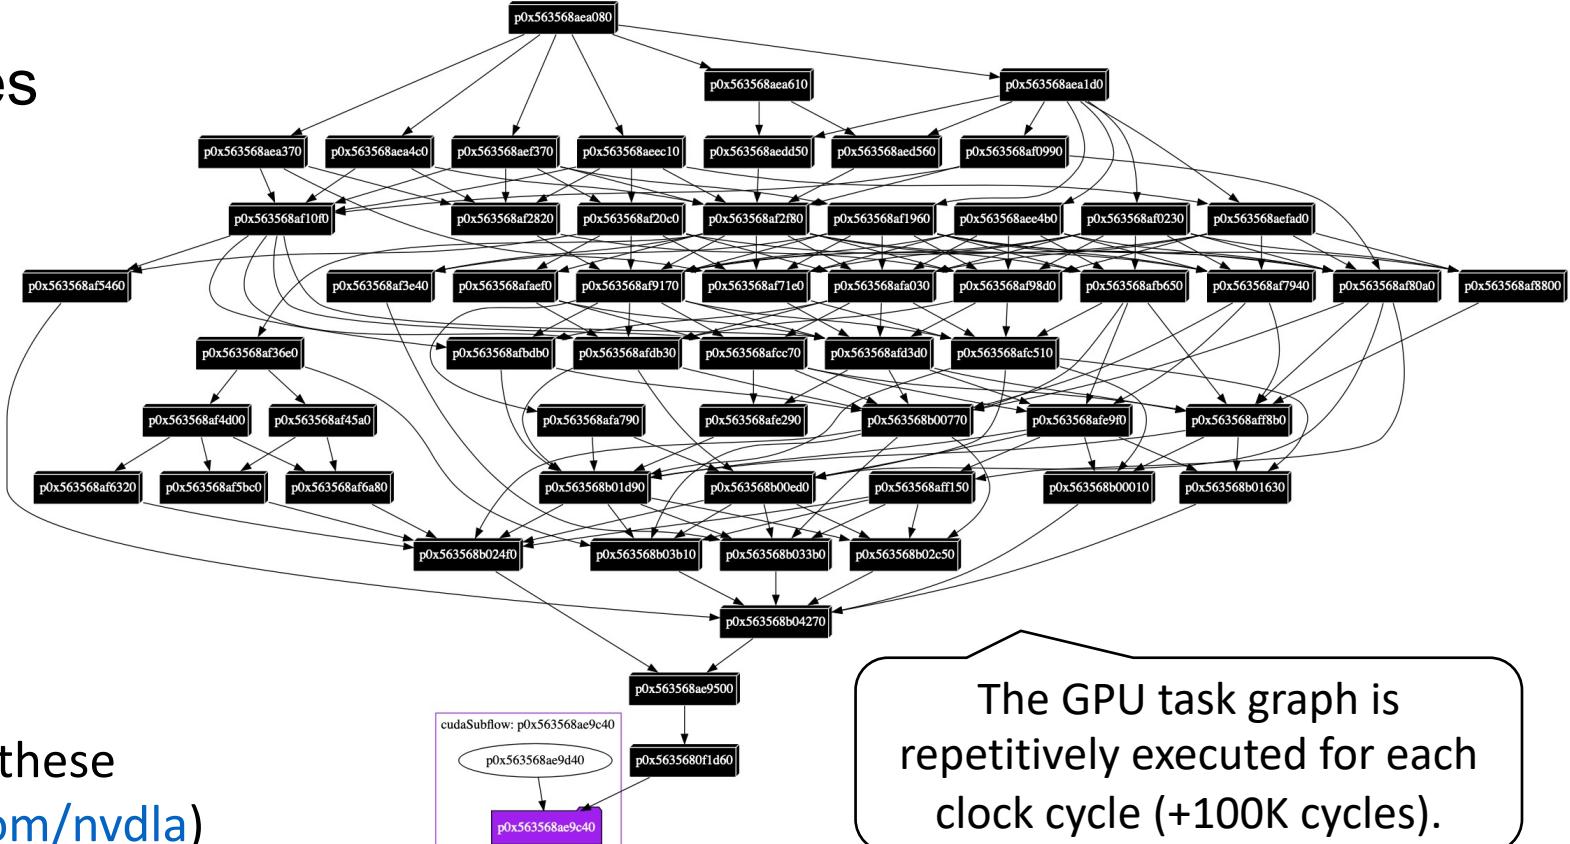

Today's Workload is Very Complex

- GPU-accelerated circuit analysis on a design of 500M gates
 - >100 kernels
 - >100 dependencies
 - >500s to finish
 - >10hrs turnaround

What are the output values of these 500M gates? (<https://github.com/nvdla>)

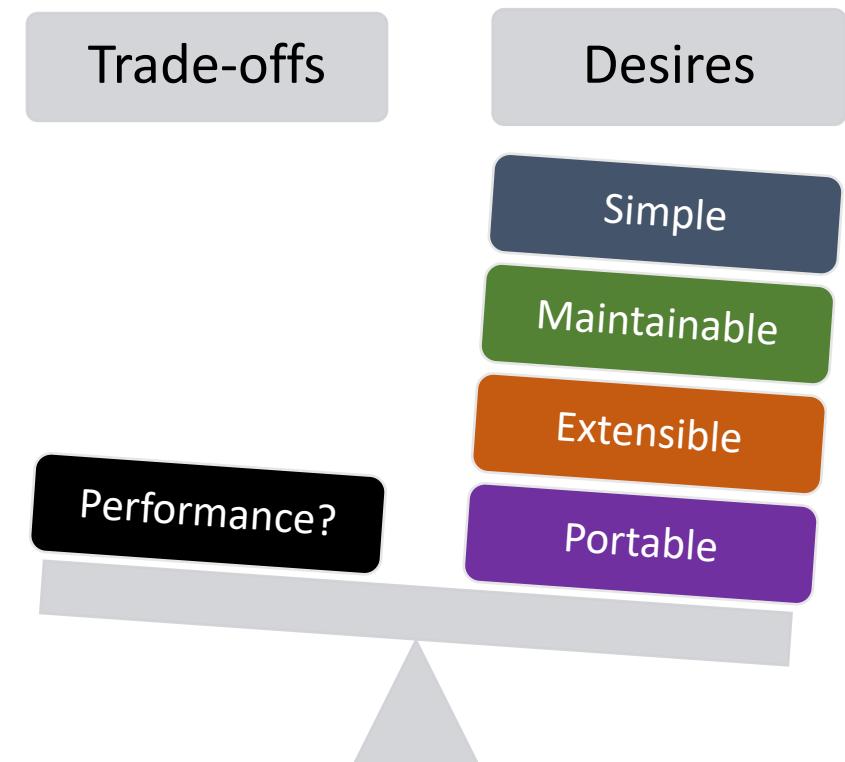

Programming is a “Big” Challenge

- You need to deal with A LOT OF technical details

- Parallelism abstraction (software + hardware)
- Concurrency control
- Task and data race avoidance
- Dependency constraints
- Scheduling efficiencies (load balancing)
- Performance portability
- ...

- And, don't forget about trade-offs

- Performance vs Desires

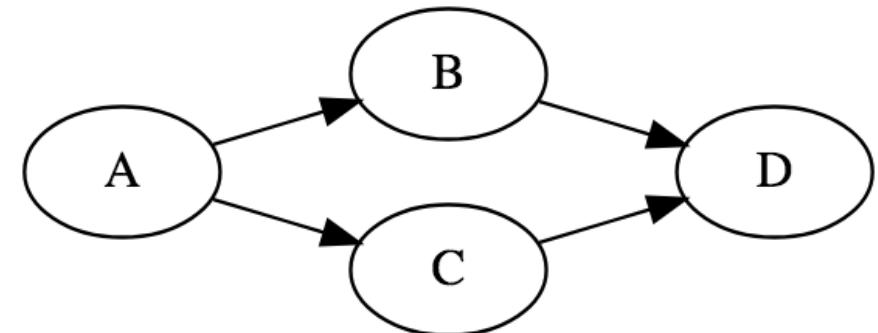

Taskflow offers a solution

*How can we make it easier for C++
developers to quickly write parallel and
heterogeneous programs with **high
performance scalability** and **simultaneous
high productivity?***

“Hello World” in Taskflow

```
#include <taskflow/taskflow.hpp> // Taskflow is header-only
int main(){
    tf::Taskflow taskflow;
    tf::Executor executor;
    auto [A, B, C, D] = taskflow.emplace(
        [] () { std::cout << "TaskA\n"; },
        [] () { std::cout << "TaskB\n"; },
        [] () { std::cout << "TaskC\n"; },
        [] () { std::cout << "TaskD\n"; }
    );
    A.precede(B, C); // A runs before B and C
    D.succeed(B, C); // D runs after B and C
    executor.run(taskflow).wait(); // submit the taskflow to the executor
    return 0;
}
```

Drop-in Integration

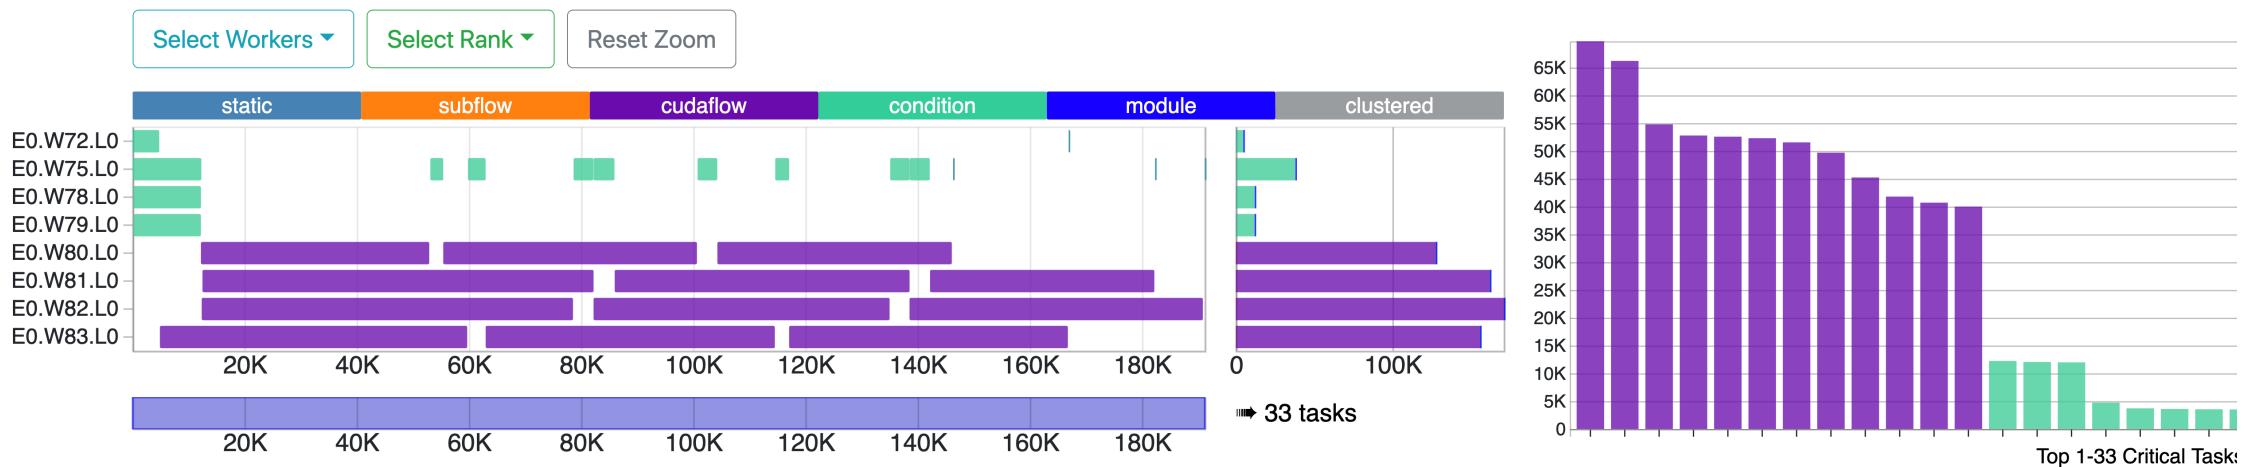

- Taskflow is header-only – *no wrangle with installation*

```
~$ git clone https://github.com/taskflow/taskflow.git # clone it only once
~$ g++ -std=c++17 simple.cpp -I taskflow/taskflow -O2 -pthread -o simple
~$ ./simple
TaskA
TaskC
TaskB
TaskD
```

Built-in Profiler/Visualizer

```
# run the program with the environment variable TF_ENABLE_PROFILER enabled
~$ TF_ENABLE_PROFILER=simple.json ./simple
~$ cat simple.json
[
  {"executor": "0", "data": [{"worker": 0, "level": 0, "data": [{"span": [172, 186], "name": "static"}]}]
}
# paste the profiling json data to https://taskflow.github.io/tfprof/
```

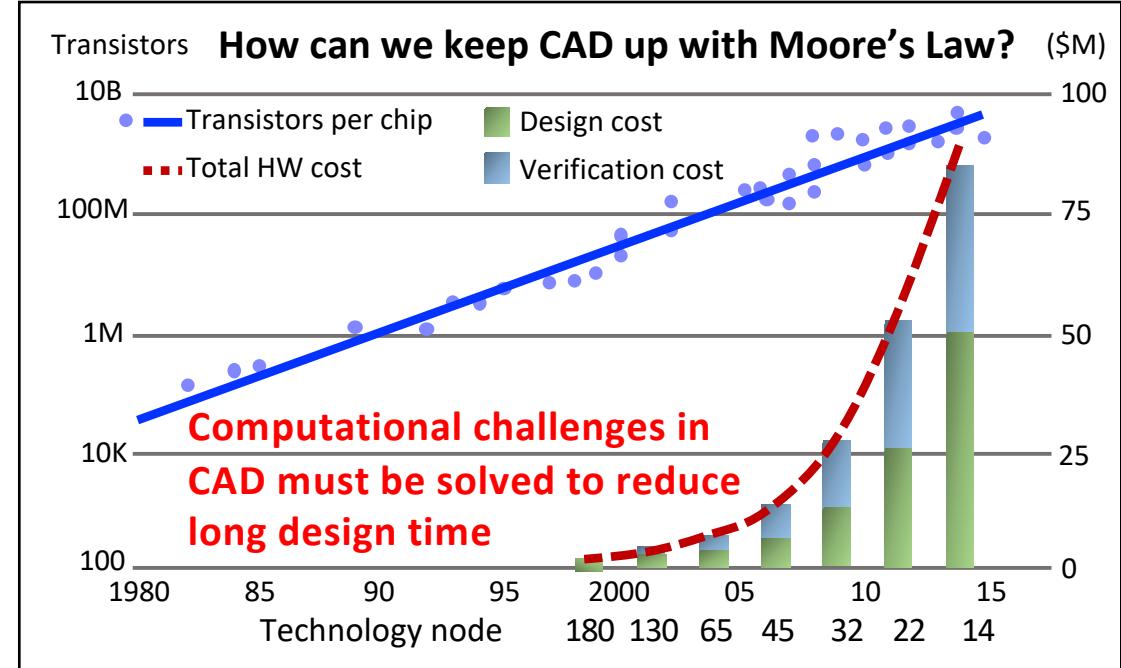

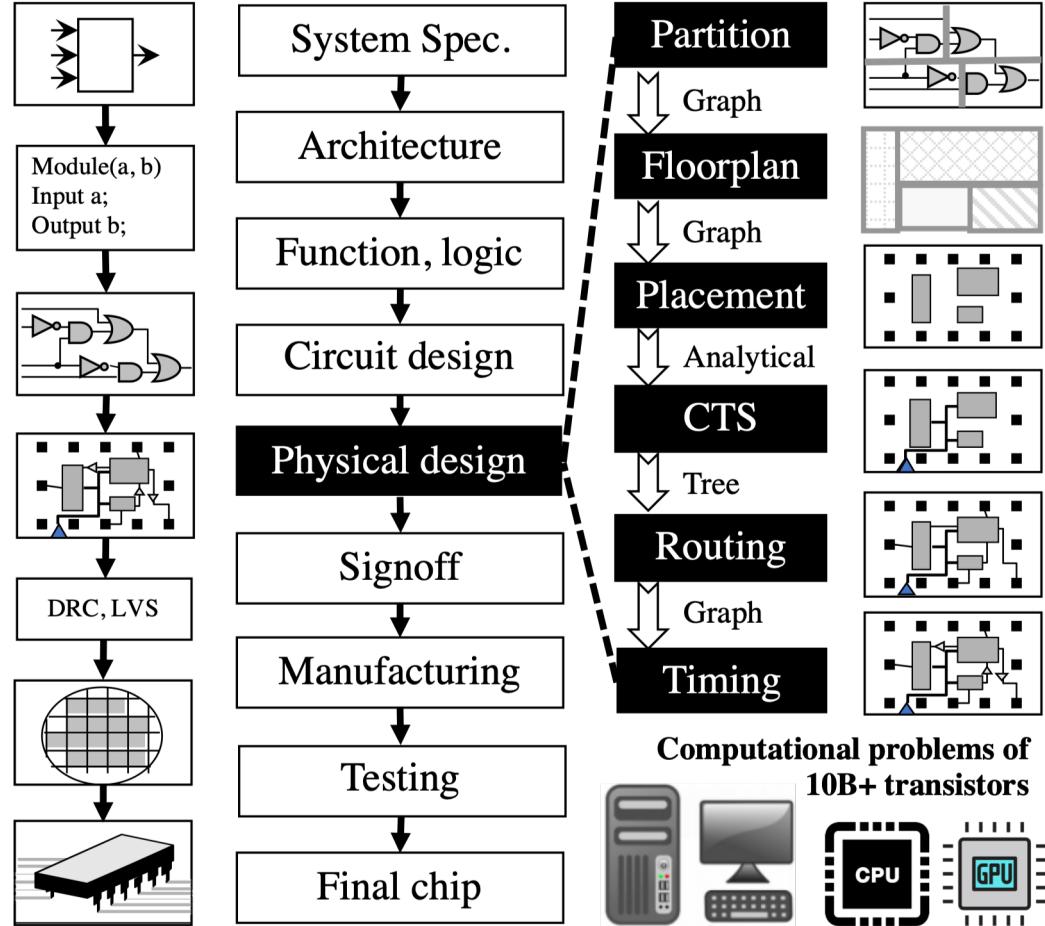

Agenda

- **Express your parallelism in the right way**
- Parallelize your applications using Taskflow
- Boost performance in real CAD applications

Our NSF CCF Project¹: Parallelizing CAD

DARPA Electronic Resurgence Initiative (ERI): <https://eri-summit.darpa.mil/>

¹: “A General-purpose Parallel and Heterogeneous Task Graph Computing System for VLSI CAD,” \$403K, 10/2021—10/2024, NSF CISE, CCF-2126672

We Invested a lot in Existing Tools ...

PaRSEC

StarPU

Two Big Problems of Existing Tools

- CAD has complex task dependencies
 - **Example:** analysis algorithms compute the circuit network of multi-millions of nodes and dependencies
 - **Problem:** existing tools are often good at loop parallelism but weak in expressing heterogeneous task graphs at this large scale
- CAD has complex control flow
 - **Example:** synthesis algorithms make essential use of *dynamic control flow* to implement various patterns
 - Combinatorial optimization (e.g., graph algorithms, discrete math)
 - analytical methods (e.g., physical synthesis)
 - **Problem:** existing tools are *directed acyclic graph* (DAG)-based and do not anticipate control flow in the graph, lacking *end-to-end* parallelism

Example: An Iterative Optimizer

- 4 computational tasks with dynamic control flow

#1: starts with init task

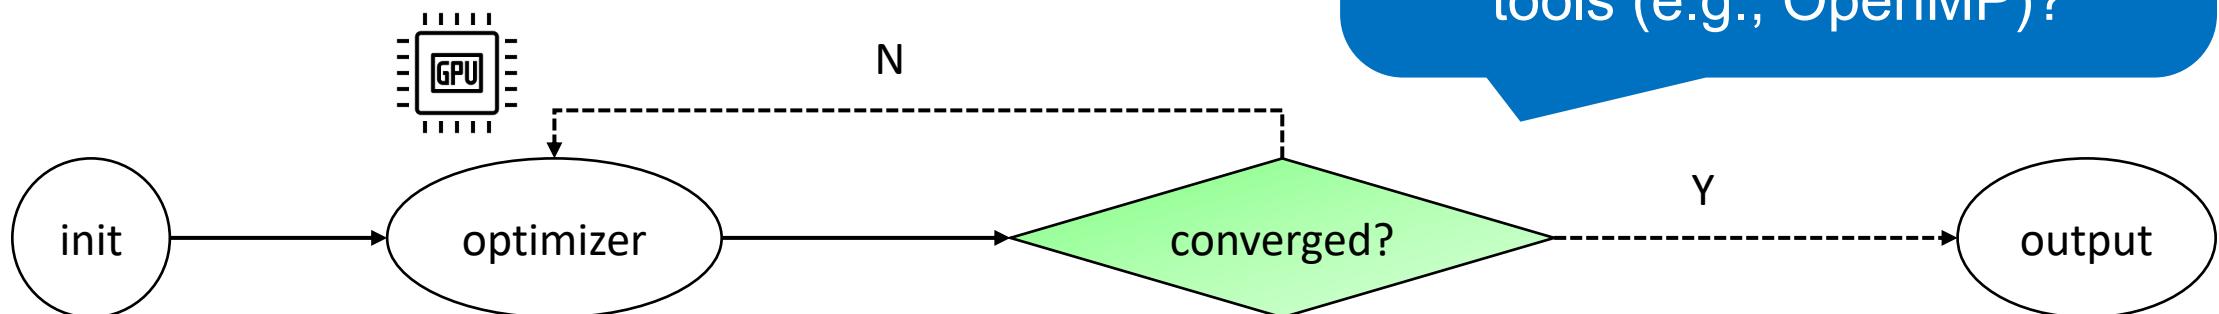

#2: enters the optimizer task (e.g., GPU math solver)

#3: checks if the optimization converged

- No: loops back to optimizer
- Yes: proceeds to stop

#4: outputs the result

How can we easily describe
this workload of dynamic
control flow using existing
tools (e.g., OpenMP)?

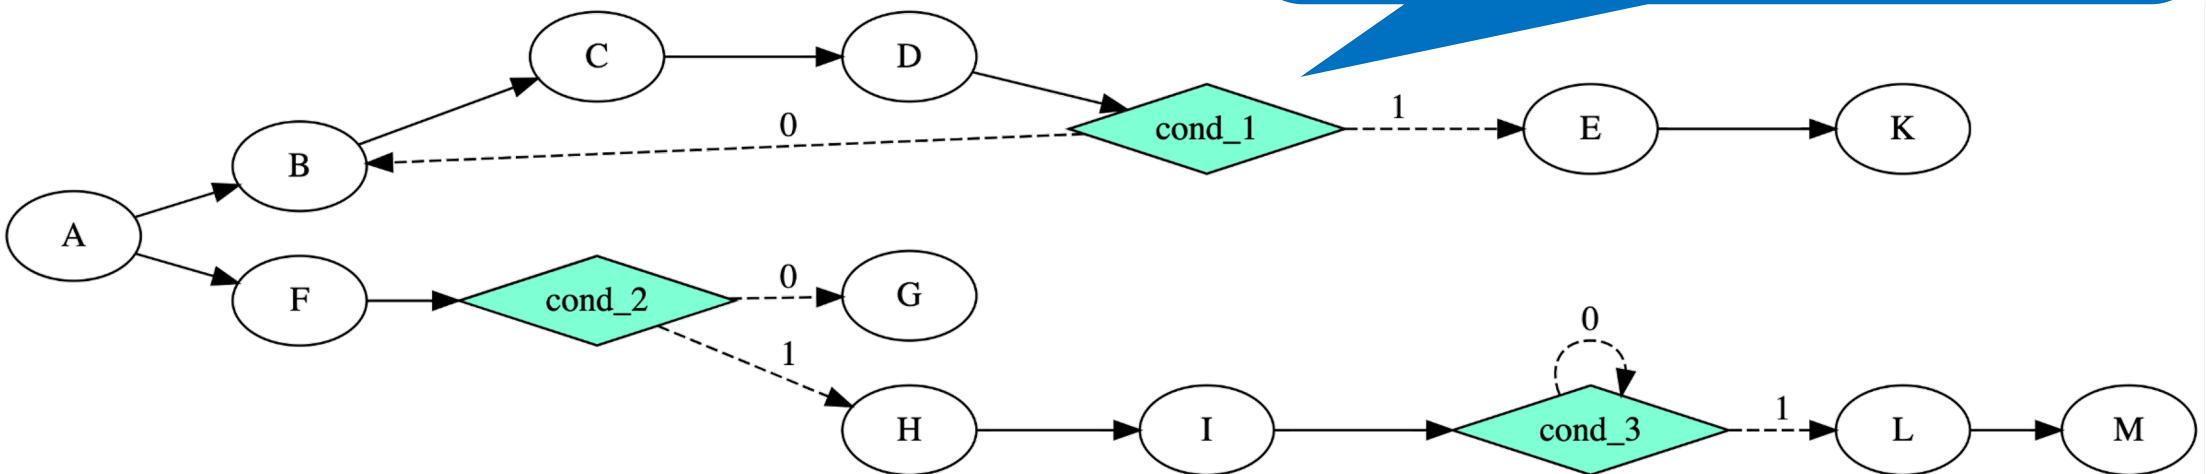

A Slightly More Complicated Example

- **Three control-flow blocks**

- cond_1: iterative control flow
- cond_2: if-else conditional tasking
- cond_3: loop

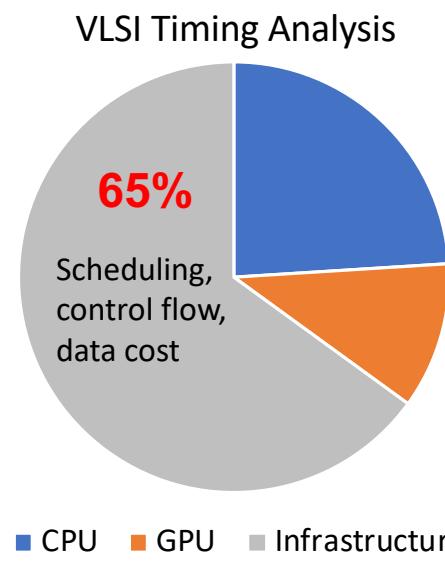

Very difficult for existing DAG-based systems to express an efficient overlap between tasks and control flow ...

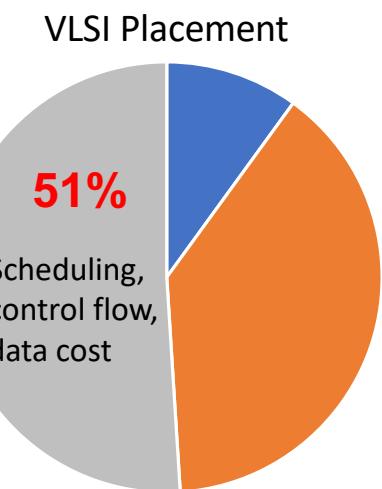

Need a New Parallel Programming System

While designing parallel algorithms is non-trivial, what makes parallel programming an enormous challenge is the **infrastructure work** of “*how to efficiently express dependent tasks along with algorithmic control flow and schedule them across heterogeneous computing resources*”

- **VLSI timing analysis (ICCAD'20)**
 - up to **65%** runtime on infrastructure
 - 24% on CPU and 11% on GPU
- **VLSI placement (TCAD'21)**
 - up to **51%** runtime on infrastructure
 - 10% on CPU and 39% on GPU

■ CPU ■ GPU ■ Infrastructure

■ CPU ■ GPU ■ Infrastructure

Agenda

- Express your parallelism in the right way
- **Parallelize your applications using Taskflow**
- Boost performance in real CAD applications

Revisit “Hello World” in Taskflow (TPDS’22)

```
#include <taskflow/taskflow.hpp> // Taskflow is header-only
int main(){
    tf::Taskflow taskflow;
    tf::Executor executor;
    auto [A, B, C, D] = taskflow.emplace(
        [] () { std::cout << "TaskA\n"; },
        [] () { std::cout << "TaskB\n"; },
        [] () { std::cout << "TaskC\n"; },
        [] () { std::cout << "TaskD\n"; }
    );
    A.precede(B, C); // A runs before B and C
    D.succeed(B, C); // D runs after B and C
    executor.run(taskflow).wait(); // submit the taskflow to the executor
    return 0;
}
```

A new **control taskflow graph (CTFG)** programming model

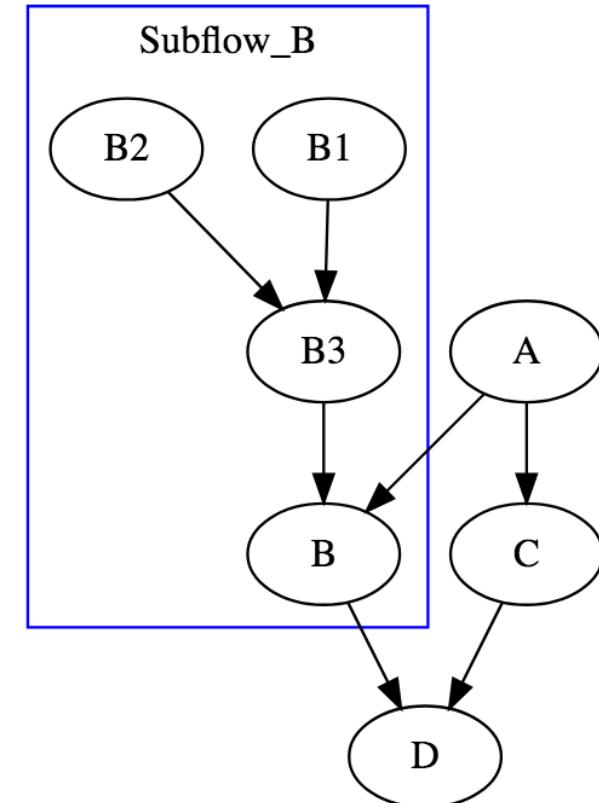

1. Static tasking
 2. Dynamic tasking
 3. Conditional tasking
 4. Heterogeneous tasking
 5. Pipeline tasking
- ... (more on <https://taskflow.github.io/>)

#2: Dynamic Tasking (Subflow)

```
// create three regular tasks
tf::Task A = tf.emplace([](){}).name("A");
tf::Task C = tf.emplace([](){}).name("C");
tf::Task D = tf.emplace([](){}).name("D");
```

```
// create a subflow graph (dynamic tasking)
tf::Task B = tf.emplace([] (tf::Subflow& subflow) {
    tf::Task B1 = subflow.emplace([](){}).name("B1");
    tf::Task B2 = subflow.emplace([](){}).name("B2");
    tf::Task B3 = subflow.emplace([](){}).name("B3");
    B1.precede(B3);
    B2.precede(B3);
}).name("B");
```

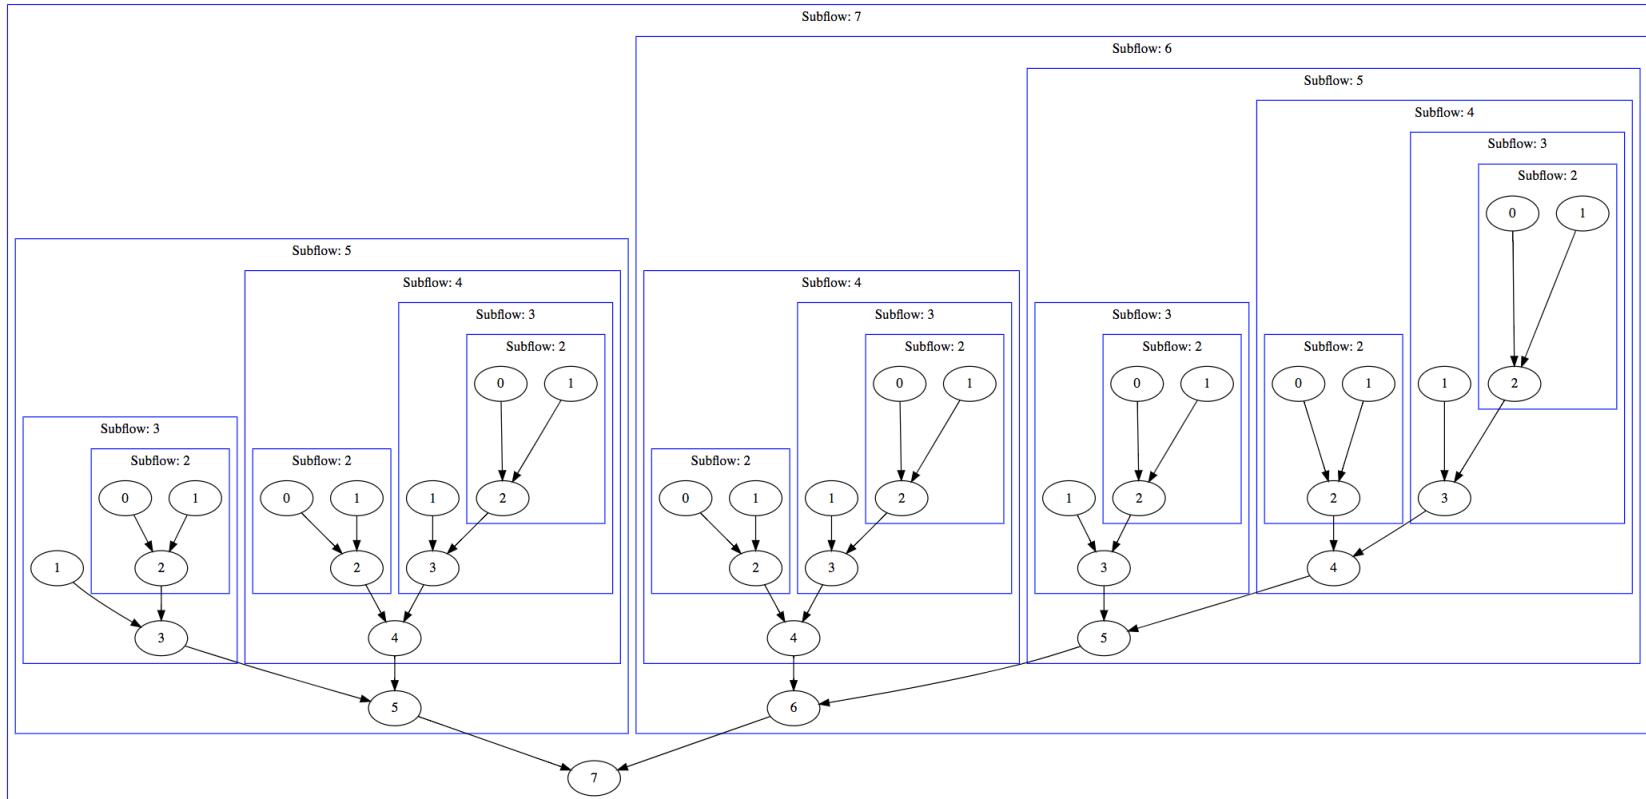

A.precede(B); // B runs after A
A.precede(C); // C runs after A
B.precede(D); // D runs after B
C.precede(D); // D runs after C

Subflow can be Nested and Recursive

- Find the 7th Fibonacci number using subflow
 - $\text{Fib}(n) = \text{Fib}(n-1) + \text{Fib}(n-2)$

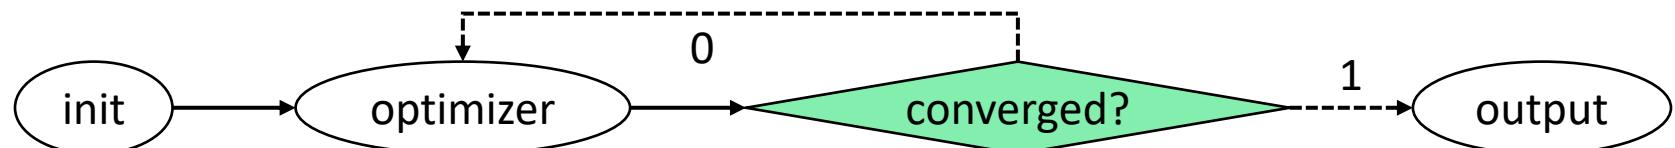

#3: Conditional Tasking (if-else)

```

auto init      = taskflow.emplace([&](){ initialize_data_structure(); } )
                  .name("init");
auto optimizer = taskflow.emplace([&](){ matrix_solver(); } )
                  .name("optimizer");
auto converged = taskflow.emplace([&](){ return converged() ? 1 : 0; } )
                  .name("converged");
auto output    = taskflow.emplace([&](){ std::cout << "done!\n"; } );
                  .name("output");

init.precede(optimizer);
optimizer.precede(converged);
converged.precede(optimizer, output); // return 0 to the optimizer again

```

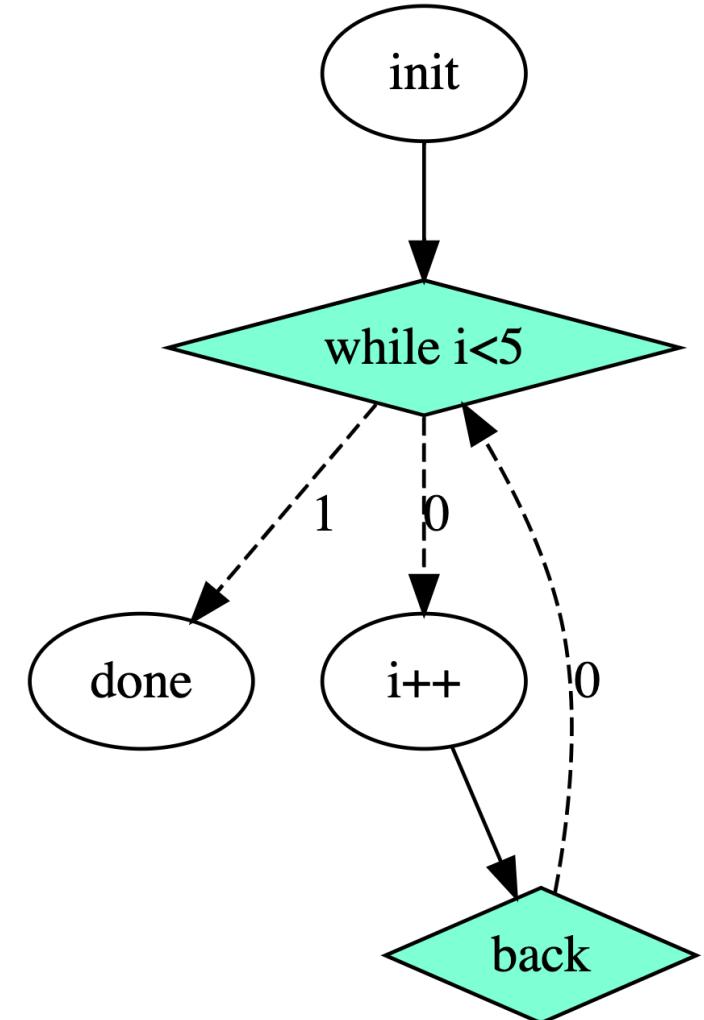

*Condition task enables in-graph control flow to achieve **end-to-end** parallelism*

#3: Conditional Tasking (iterative loop)

```

tf::Taskflow taskflow;
int i;
auto [init, cond, body, back, done] = taskflow.emplace(
    [&](){ std::cout << "i=0"; i=0; },
    [&](){ std::cout << "while i<5\n"; return i < 5 ? 0 : 1; },
    [&](){ std::cout << "i++=" << i++ << '\n'; },
    [&](){ std::cout << "back\n"; return 0; },
    [&](){ std::cout << "done\n"; }
);
init.precede(cond);
cond.precede(body, done);
body.precede(back);
back.precede(cond);

```

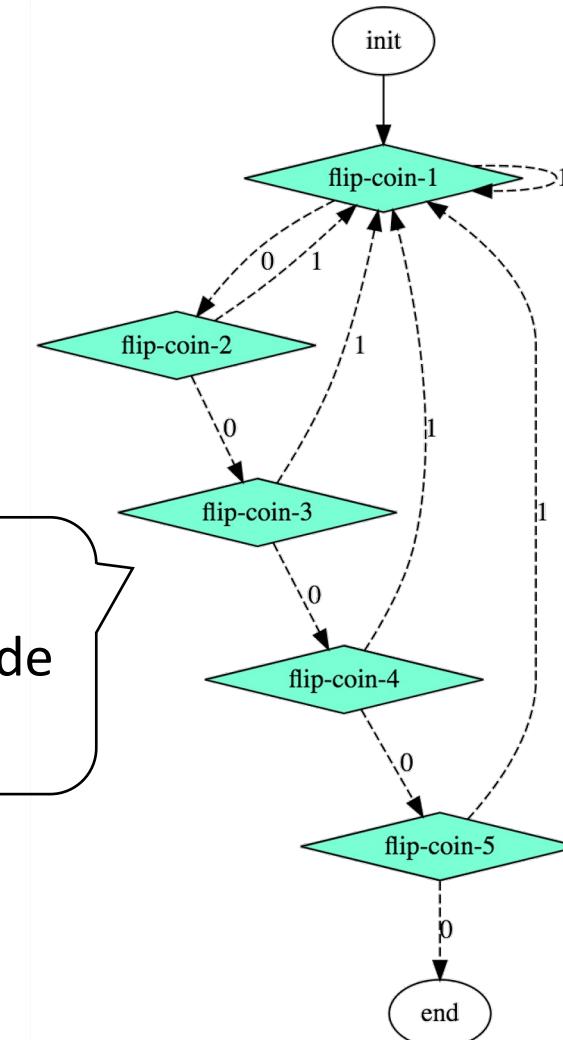

#3: Conditional Tasking (random loops)

```
auto A = taskflow.emplace([&](){ } );
auto B = taskflow.emplace([&](){ return rand()%2; } );
auto C = taskflow.emplace([&](){ return rand()%2; } );
auto D = taskflow.emplace([&](){ return rand()%2; } );
auto E = taskflow.emplace([&](){ return rand()%2; } );
auto F = taskflow.emplace([&](){ return rand()%2; } );
auto G = taskflow.emplace([&]());
```

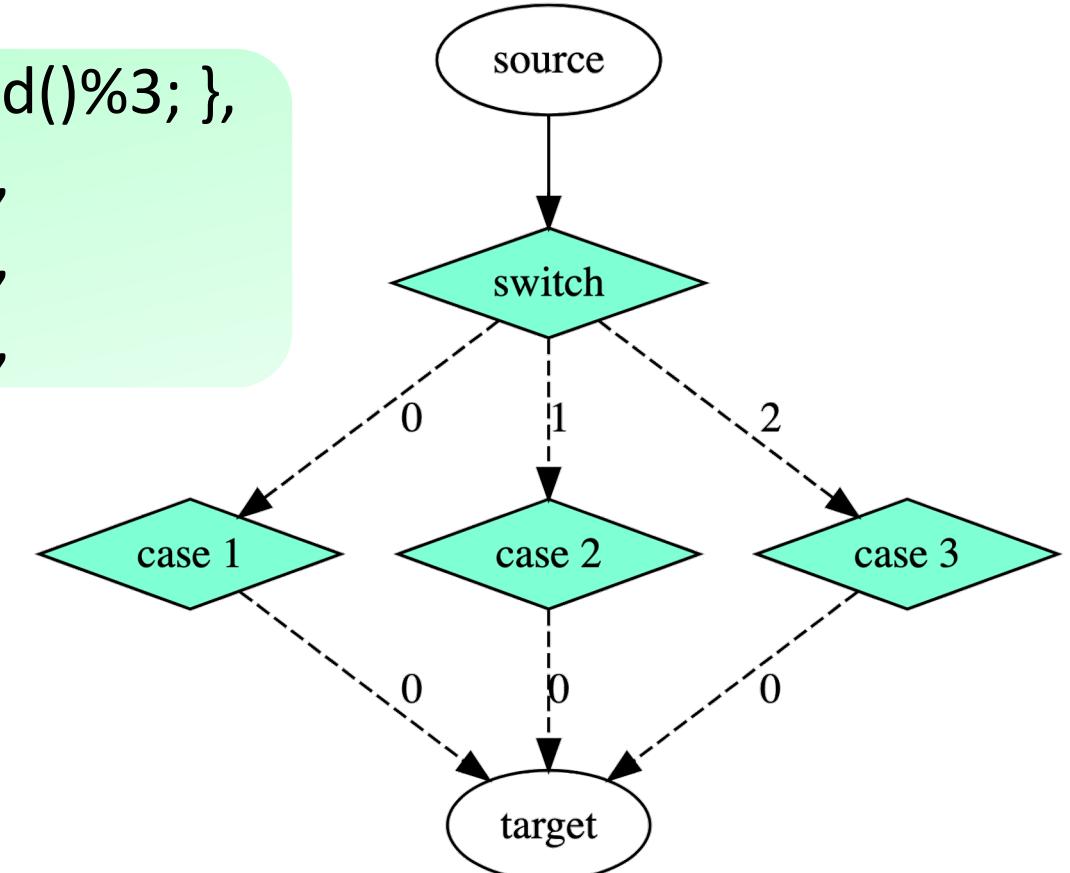

- A.`precede(B).name("init");`
- B.`precede(C, B).name("flip-coin-1");`
- C.`precede(D, B).name("flip-coin-2");`
- D.`precede(E, B).name("flip-coin-3");`
- E.`precede(F, B).name("flip-coin-4");`
- F.`precede(G, B).name("flip-coin-5");`
- G.`name("end");`

Each task flips a binary coin to decide the next path

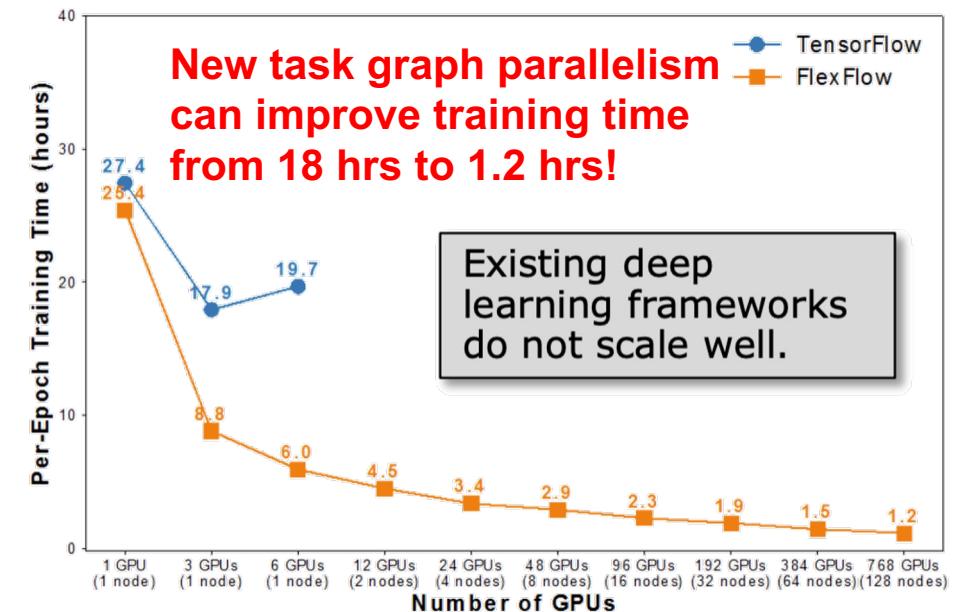

#3: Conditional Tasking (Switch)

```
auto [source, swcond, case1, case2, case3, target] = taskflow.emplace(
    [](){ std::cout << "source\n"; },
    [](){ std::cout << "switch\n"; return rand()%3; },
    [](){ std::cout << "case 1\n"; return 0; },
    [](){ std::cout << "case 2\n"; return 0; },
    [](){ std::cout << "case 3\n"; return 0; },
    [](){ std::cout << "target\n"; }
);
source.precede(swcond);
swcond.precede(case1, case2, case3);
target.succeed(case1, case2, case3);
```

Existing Frameworks on Control Flow?

- **Expand a task graph across fixed-length iterations**
 - Large graph size linearly proportional to decision points
- **Unknown or non-deterministic iterations?**
 - Expensive dynamic tasks executing “if-else” on the fly
- **Dynamic control-flow tasks?**
 - Client-side partition
- **Same problem in large-scale ML**
 - TensorFlow with RNN (EuroSys’18)
 - FlexFlow (MLSys’19, ICML’18)
 - DGL (CoRR’19)
 - DOE 2022 funding preview (Dr. Finkel)

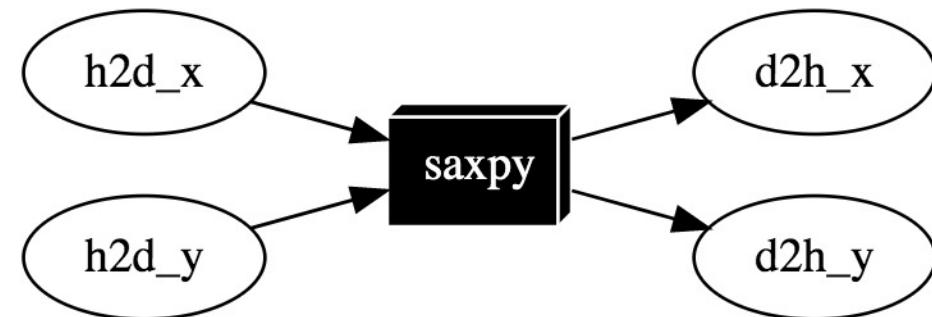

#4: Heterogeneous Tasking

```
// saxpy (single-precision A·X Plus Y) kernel
__global__ void saxpy(int n, float a, float *x, float *y) {
    if (int i = blockIdx.x*blockDim.x + threadIdx.x; i < n) {
        y[i] = a*x[i] + y[i];
    }
}
```

cudaFlow automatically transforms an application GPU task graph to an optimized “CUDA graph”

```
// create an explicit saxpy task graph using cudaFlow
tf::cudaFlow cf;
tf::cudaTask h2d_x = cf.copy(dx, hx, N);
tf::cudaTask h2d_y = cf.copy(dy, hy, N);
tf::cudaTask d2h_x = cf.copy(hx, dx, N);
tf::cudaTask d2h_y = cf.copy(hy, dy, N);
tf::cudaTask saxpy = cf.kernel((N+255)/256, 256, 0, saxpy, N, 2.0f, dx, dy);
kernel.succeed(h2d_x, h2d_y).precede(d2h_x, d2h_y);
```

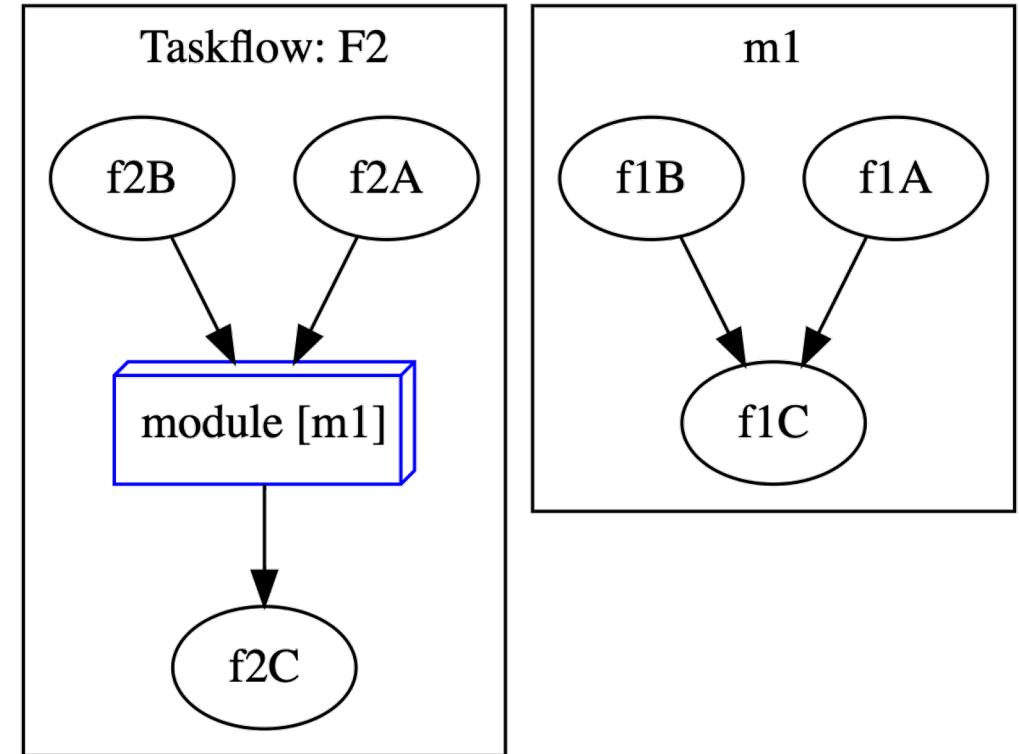

5: Composable Tasking

```

tf::Taskflow f1, f2;
auto [f1A, f1B] = f1.emplace(
    []() { std::cout << "Task f1A\n"; },
    []() { std::cout << "Task f1B\n"; }
);
auto [f2A, f2B, f2C] = f2.emplace(
    []() { std::cout << "Task f2A\n"; },
    []() { std::cout << "Task f2B\n"; },
    []() { std::cout << "Task f2C\n"; }
);
auto f1_module_task = f2.composed_of(f1);
f1_module_task.succeed(f2A, f2B)
    .precede(f2C);

```

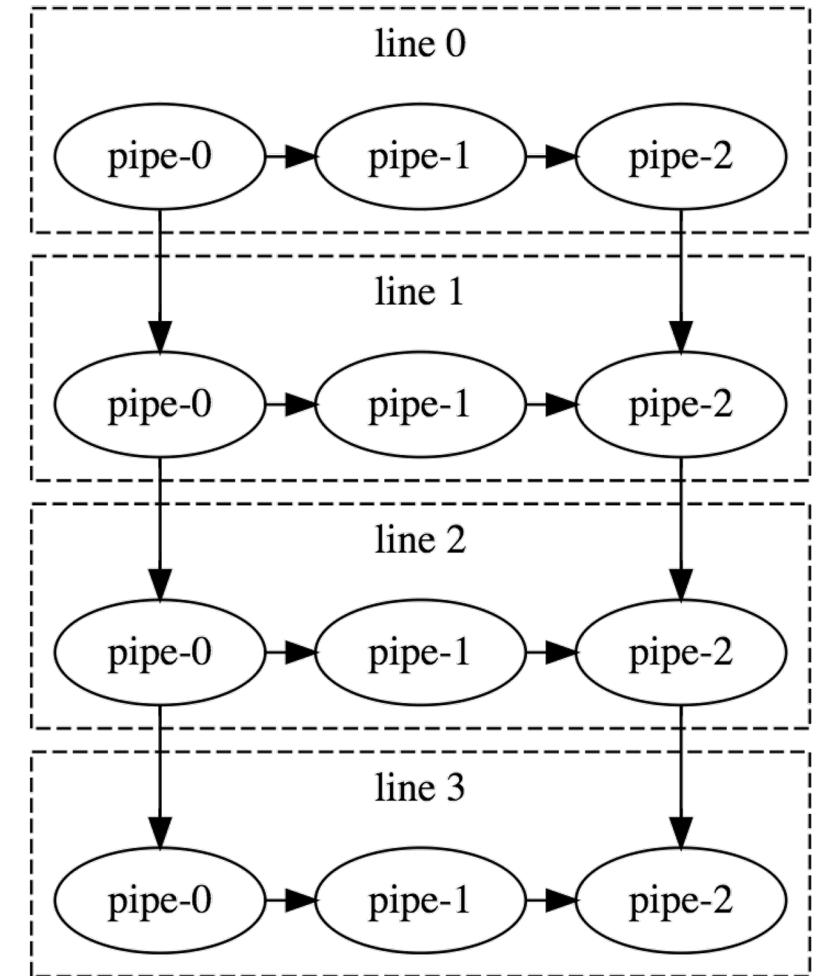

5: Pipeline Tasking (HPDC'22)

```

std::array<int, 4> buffer;
tf::Pipeline pl(4,
    tf::Pipe {tf::PipeType::SERIAL, [&buffer]}(tf::Pipeflow & pf) {
        if (pf.token() == 5) {
            pf.stop();
            return;
        }
        buffer[pf.line()] = pf.token();
    },
    tf::Pipe {tf::PipeType::PARALLEL, [&buffer]}(tf::Pipeflow & pf) {
        buffer[pf.line()] = buffer[pf.line()] + 1;
    },
    tf::Pipe {tf::PipeType::SERIAL, [&buffer]}(tf::Pipeflow & pf) {
        buffer[pf.line()] = buffer[pf.line()] + 1;
    }
);
auto task = taskflow.composed_of(pl);
executor.run(taskflow).wait();

```

Submit Taskflow to Executor

- Executor manages a set of threads to run taskflows
 - All execution methods are *non-blocking*
 - All execution methods are *thread-safe*

```
{  
    tf::Taskflow taskflow1, taskflow2, taskflow3;  
    tf::Executor executor;  
    // create tasks and dependencies  
    // ...  
    auto future1 = executor.run(taskflow1);  
    auto future2 = executor.run_n(taskflow2, 1000);  
    auto future3 = executor.run_until(taskflow3, [i=0](){ return i++>5 });  
    executor.wait_for_all(); // wait for all the above tasks to finish  
}
```

Everything is Composable in Taskflow

- End-to-end parallelism in one graph
 - Task, dependency, control flow all together
 - Scheduling with whole-graph optimization
 - Efficient overlap among heterogeneous tasks
- Largely improved productivity!

Reddit: <https://www.reddit.com/r/cpp/> [under taskflow]

I've migrated <https://ossia.io> from TBB flow graph to taskflow a couple weeks ago. Net +8% of throughput on the graph processing itself, and took only a couple hours to do the change! Also don't have to fight with building the TBB libraries for 30 different platforms and configurations since it's header only.

(TPDS'22)

Dynamic Task Graph Parallelism

```
tf::Executor executor;  
tf::AsyncTask A = executor.silent_dependent_async([](){ printf("A\n"); });  
tf::AsyncTask B = executor.silent_dependent_async([](){ printf("B\n"); }, A);  
tf::AsyncTask C = executor.silent_dependent_async([](){ printf("C\n"); }, A);  
auto [D, fuD] = executor.dependent_async([](){ printf("D\n"); }, B, C);  
fuD.get(); // wait for D to finish, which in turns means A, B, C finish
```

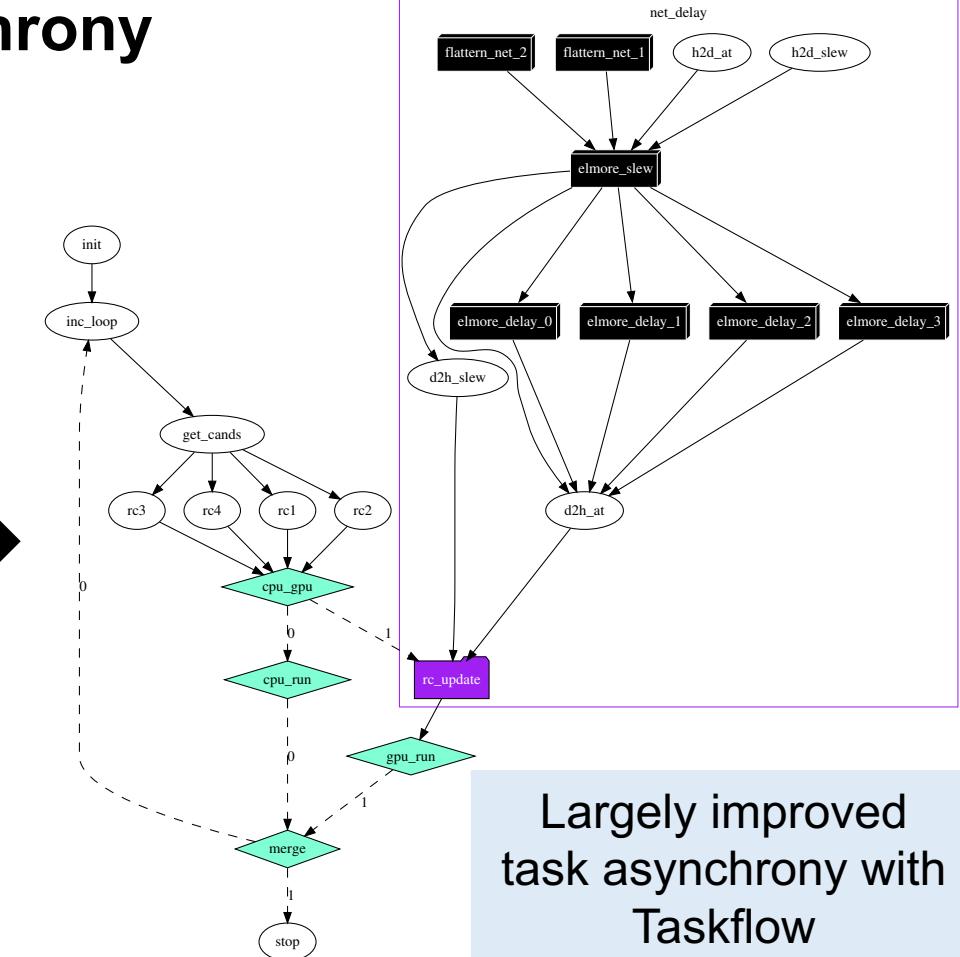

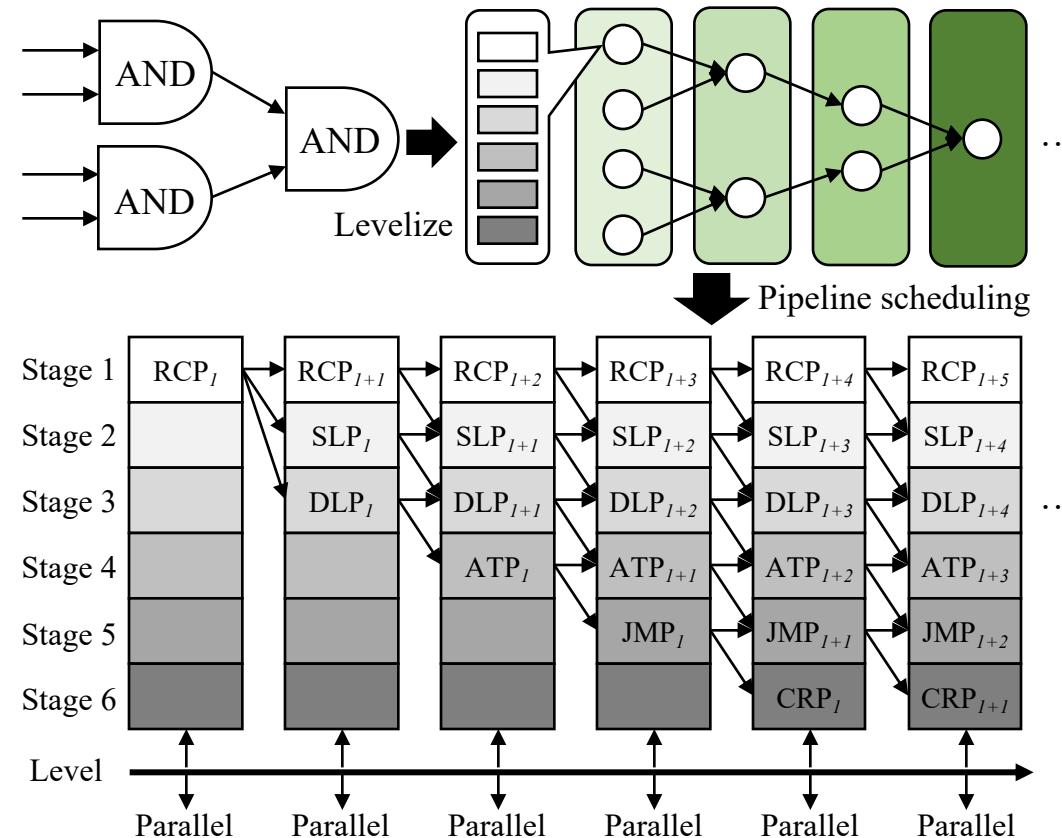

Agenda

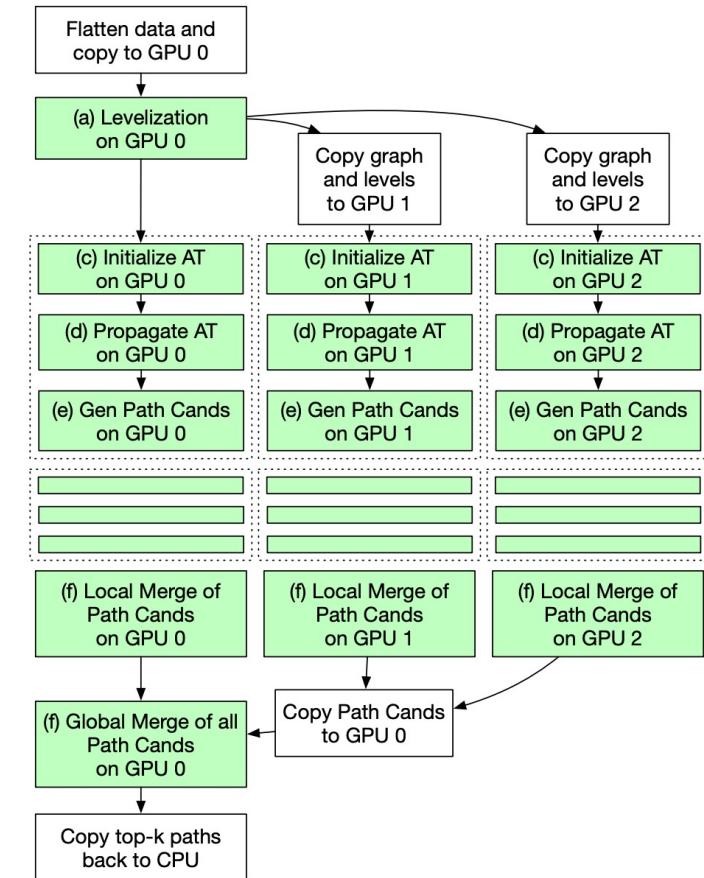

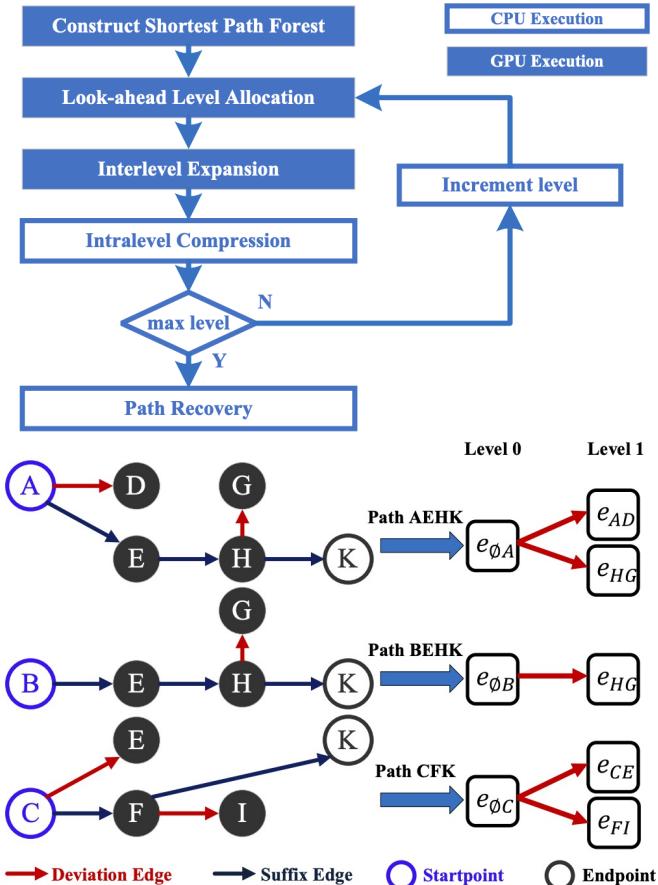

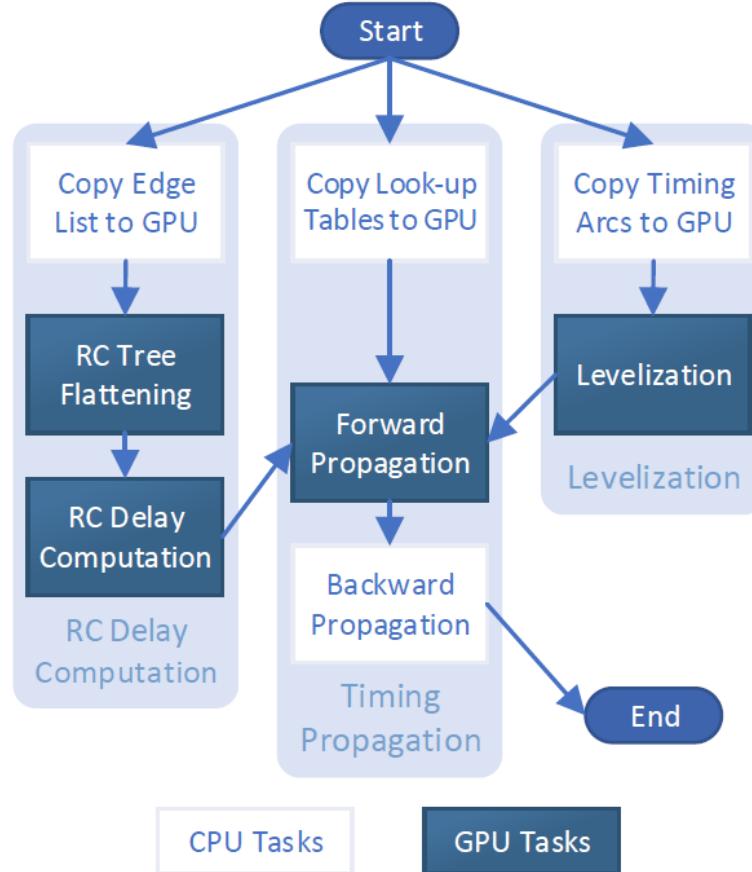

- Express your parallelism in the right way
- Parallelize your applications using Taskflow
- **Boost performance in real CAD applications**

Case Study 1: Timing Analysis (TCAD'21)

- Taskflow largely improves task asynchrony

Case Study 1: Timing Analysis (cont'd)

GPU-based graph analysis (ICCAD'20)

GPU-based path analysis (DAC'21)

GPU-based CPPR (ICCAD'21)

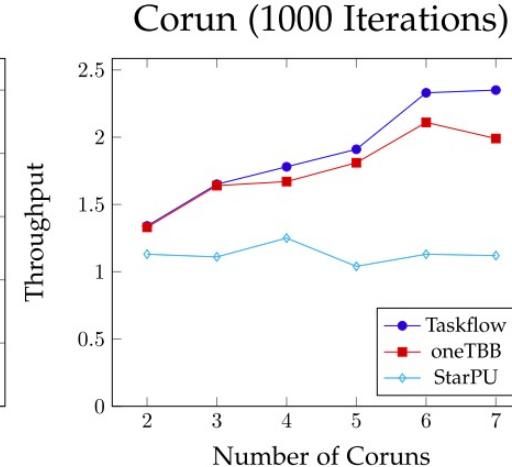

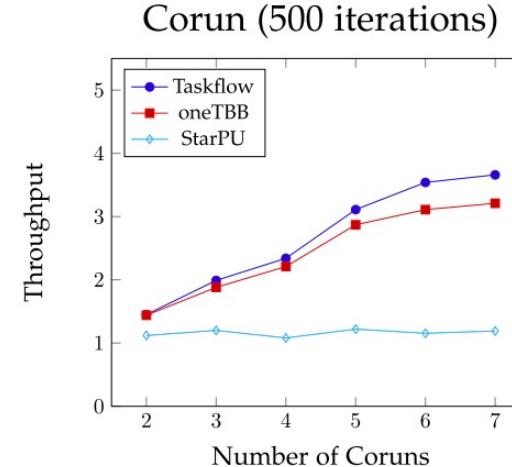

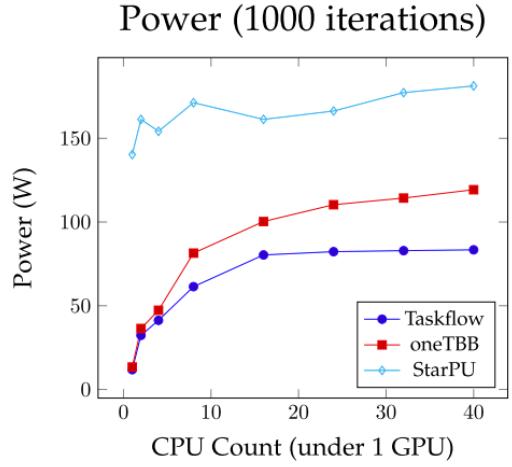

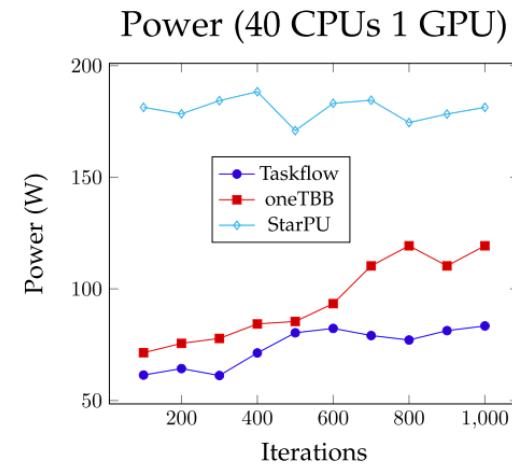

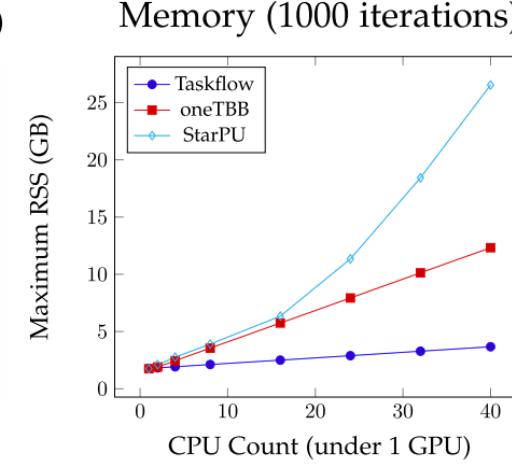

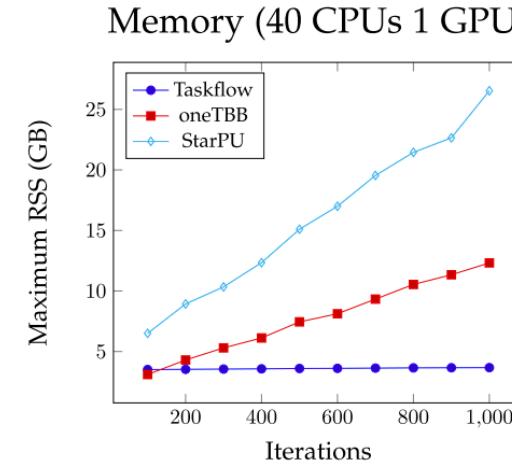

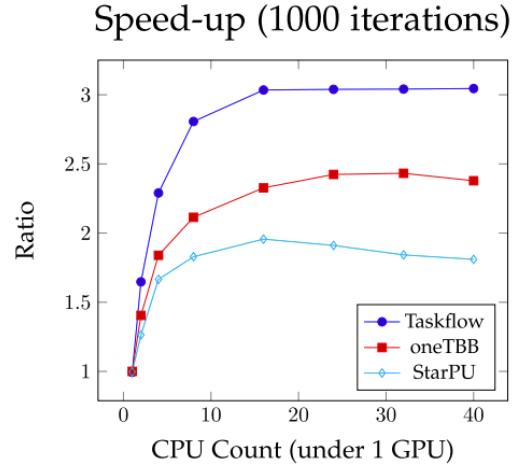

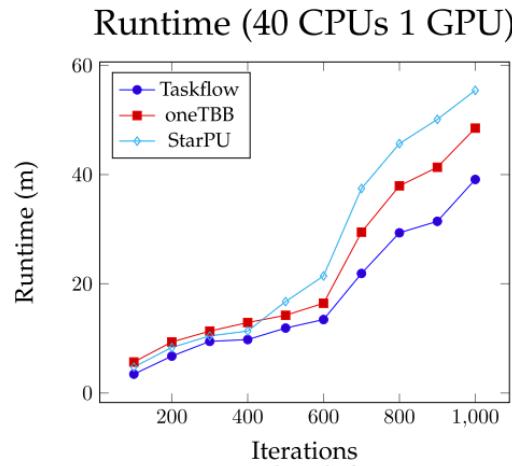

Case Study 1: Timing Analysis (DAC'21)

- Applied Taskflow to accelerate path-based analysis on GPU
 - Ex: leon3mp (1.6M gates): **611x speed-up** over 1 CPU (**44x** over 40 CPUs)
 - **Best paper award in TAU 2021**
